

# CSS Interview Questions for 2 Years Experience

**Q: What is specificity in CSS and how is it calculated?**

A: Specificity determines which CSS rule is applied by the browser. It is calculated based on the number of ID selectors (100), class/attribute/pseudo-class selectors (10), and type/pseudo-element selectors (1). Inline styles score 1000.

**Q: Explain Flexbox and how it is different from Grid.**

A: Flexbox is one-dimensional (row or column) and best for aligning items along a single axis. Grid is two-dimensional and allows control over rows and columns simultaneously.

**Q: What is stacking context in CSS?**

A: A stacking context is formed by elements with position relative/absolute/fixed with z-index, and affects how elements are layered on top of each other.
